Abstract

Presents some results found in [1]

1 Introduction

Theorem 1 (Absolutely continuous w.r.t Lebesgue measure). *We say that a measure μ on $\mathcal{B}(\mathbb{R}^d)$ is absolutely continuous with respect to the Lebesgue measure λ if for all $A \in \mathcal{B}(\mathbb{R}^d)$ and $m(A) = 0$ then $\mu(A) = 0$.*

Corollary 2. *Let μ be absolutely continuous with respect to the Lebesgue measure, then for any $A \in \mathcal{B}(\mathbb{R}^d)$, denoting the density function of μ by f we have*

$$\mu(A) = \int_A f dx$$

Definition 3 (Random Voronoi Tessellation). Let $X_1, \dots, X_n$ be i.i.d random vectors taking values in $\mathbb{R}^d$. That means all of them share a common distribution, call it μ . We assume that μ is absolutely continuous with respect to the Lebesgue measure λ , and denote the density function of μ by f . These X_i 's define a partition of $\mathbb{R}^d$ into n sets $S_1, \dots, S_n$ such that S_i contain all points in $\mathbb{R}^d$ whose distances to X_i is not greater than their distances to all other X_j 's ($j \neq i$). Letting $\|\cdot\|$ denote the standard Euclidean norm, we have that

$$S_i = \{x \in \mathbb{R}^d : \|x - X_i\| = \min_{j=1, \dots, n} \|x - X_j\|\} \cap \{x \in \mathbb{R}^d : \|x - X_i\| < \min_{j=1, \dots, i-1} \|x - X_j\|\}$$

Proposition 4 (Asymptotic second moment). *The asymptotic second moment is expressed in terms of a random variable W defined as follows. Let Y be a random vector uniformly distributed in $B(0, 1)$. Define, $\vec{1} = (1, 0, 0, \dots, 0) \in \mathbb{R}^d$ and let $\overline{B} = B(\vec{1}, 1) \cup B(Y, \|Y\|)$. *Is this assuming standard Euclidean norm?**

We introduce the random variable

$$W = \frac{m(\overline{B})}{m(B(0, 1))}$$

and let

$$\alpha(d) \equiv \mathbb{E} \left[\frac{2}{W^2} \right]$$

Theorem 5. *Assume μ has density f . Then*

$$n\mathbb{E}[\mu(S_1) : X_1 = x] \rightarrow 1$$

for μ almost all x .

Proof. Observe that

$$\mathbb{E}(\mu(S_1) : X_1 = x) = \mathbb{P}\{X_{n+1} \in S_1 : X_1 = x\}$$

Where we used a neat trick to interchange $\mu(S_1)$ with $X_{n+1} \in S_1$ since X_{n+1} is μ distributed the probability of it landing in S_1 is the same as the μ measure of S_1 . Furthermore we have that

$$\mathbb{P}(X_{n+1} \in S_1 : X_1 = x) = \mathbb{P} \left(\bigcap_{i=2}^n \{X_i \notin B(X_{n+1}, \|X_{n+1} - x\|)\} \right)$$

This is because since $X_{n+1} \in S_1$ so it must be at least $\|X_{n+1} - x\|$ distance away from any other X_i ($i \geq 2$). Defining $Z(x) = \mu(B(X, \|X - x\|))$ and since all the X_i 's are independently distributed, we get that

$$\mathbb{P} \left(\bigcap_{i=2}^n \{X_i \notin B(X_{n+1}, \|X_{n+1} - x\|)\} \right) = \mathbb{E}[(1 - Z(x))^{n-1}]$$

□

$$Z(x) = \mu(B(X, \|X - x\|))$$
